3. Project Design Phase

1. Introduction

The **Project Design Phase** defines how the Auto Ticket Classification system will work. The main objective is to design a **ServiceNow Flow Designer workflow** that automatically analyzes incoming tickets and classifies them based on their category, priority, and type.

2. System Design

Input:
User creates an incident/ticket with details such as:

- Short Description
- Description
- Category
- Priority
- Caller/User

Flow Designer Process:

New Ticket Created

↓

Trigger: Incident Created

↓

Read Ticket Details

↓

Analyze Description / Keywords

↓

Classify Ticket

↓

Set Category & Subcategory

↓

Determine Priority

↓

Assign Assignment Group

↓

Update Ticket

↓

Notify Assigned Team

3. Flow Designer Components

Component	Purpose
Trigger	Starts the flow when a new ticket is created
Get/Read Record	Retrieves ticket information
Flow Logic	Checks ticket conditions and keywords
If/Else	Determines the appropriate classification
Update Record	Updates category, priority and assignment group
Notification	Sends notification to the responsible team

4. Example Classification If

the ticket description is:

“My laptop is not connecting to Wi-Fi.” The

Flow Designer can classify it as:

- **Category:** Network
- **Subcategory:** Wi-Fi
- **Priority:** Medium
- **Assignment Group:** Network Support

5. Design Considerations

- Use clear classification rules.

- Avoid assigning tickets to incorrect groups.
- Provide a default category for unrecognized tickets.
- Maintain an audit trail of automatic changes.
- Allow support staff to manually correct classifications when required.

6. Expected Output

The designed flow automatically converts an unclassified ticket into a properly classified ticket, reducing manual work and helping support teams handle incidents efficiently.

Project Design Phase → Trigger → Classification Logic → Ticket Update → Assignment → Notification
